COMP 790: OS Implementation

Last time...

- We've discussed how the OS schedules the CPU
 - And how to block a process on a resource (disk, network)
- Today:
 - How do processes block on each other?
 - And more generally communicate?

4

4

THE UNIVERSITY OF NORTH CAROLINA AT CHAPEL HILL

COMP 790: OS Implementation

Outline

- Signals
 - Overview and APIs
 - Handlers
 - Kernel-level delivery
 - Interrupted system calls
- Interprocess Communication (IPC)
 - Pipes and FIFOs
 - System V IPC
 - Windows Analogs

5

5

THE UNIVERSITY OF NORTH CAROLINA AT CHAPEL HILL

COMP 790: OS Implementation

What is a signal?

- Like an interrupt, but for applications
 - <64 numbers with specific meanings
 - A process can raise a signal to another process or thread
 - A process or thread registers a handler function
- For both IPC and delivery of hardware exceptions
 - Application-level handlers: divzero, segfaults, etc.
- No "message" beyond the signal was raised
 - And maybe a little metadata
 - PID of sender, faulting address, etc.
 - But platform-specific (non-portable)

6

6

THE UNIVERSITY of NORTH CAROLINA at CHAPEL HILL COMP 790: OS Implementation

Example

```

int main() {
    ...
    signal(SIGUSR1, &usr_handler);
    ...
}
    
```

Register usr_handler() to handle SIGUSR1

7

THE UNIVERSITY of NORTH CAROLINA at CHAPEL HILL COMP 790: OS Implementation

Example

```

int main() {
    ...
}

int usr_handler() { ...
}

kill(300, SIGUSR1);
    
```

Send signal to PID 300

8

THE UNIVERSITY of NORTH CAROLINA at CHAPEL HILL COMP 790: OS Implementation

Basic Model

- Application registers handlers with signal or sigaction
- Send signals with kill and friends
 - Or raised by hardware exception handlers in kernel
- Signal delivery jumps to signal handler
 - Irregular control flow, similar to an interrupt

API names are admittedly confusing

9

THE UNIVERSITY of NORTH CAROLINA at CHAPEL HILL COMP 790: OS Implementation

Signal Types

- See man 7 signal for the full list: (varies by sys/arch)
- SIGTSTP – 1 – Stop typed at terminal (Ctrl+Z)
- SIGKILL – 9 – Kill a process, for realzies
- SIGSEGV – 11 – Segmentation fault
- SIGPIPE – 13 – Broken pipe (write with no readers)
- SIGALRM – 14 – Timer
- SIGUSR1 – 10 – User-defined signal 1
- SIGCHLD – 17 – Child stopped or terminated
- SIGSTOP – 19 – Stop a process
- SIGCONT – 18 – Continue if stopped

10

THE UNIVERSITY of NORTH CAROLINA at CHAPEL HILL COMP 790: OS Implementation

Language Exceptions

- Signals are the underlying mechanism for Exceptions and catch blocks
- JVM or other runtime system sets signal handlers
 - Signal handler causes execution to jump to the catch block

11

THE UNIVERSITY of NORTH CAROLINA at CHAPEL HILL COMP 790: OS Implementation

Signal Handler Control Flow

Figure 11-2. Catching a signal

From *Understanding the Linux Kernel*

12

THE UNIVERSITY of NORTH CAROLINA at CHAPEL HILL COMP 790: OS Implementation

Alternate Stacks

- Signal handlers execute on a different stack than program execution.
 - Why?
 - Safety: App can ensure stack is actually mapped
 - And avoid assumptions about application not using space below `rsp`
 - Set with `sigaltstack()` system call
 - Like an interrupt handler, kernel pushes register state on interrupt stack
 - Return to kernel with `sigreturn()` system call
 - App can change its own on-stack register state!

13

13

THE UNIVERSITY of NORTH CAROLINA at CHAPEL HILL COMP 790: OS Implementation

Nested Signals

- What happens when you get a signal in the signal handler?
- And why should you care?

14

14

THE UNIVERSITY of NORTH CAROLINA at CHAPEL HILL COMP 790: OS Implementation

The Problem with Nesting

```

int main() {
    /* ... */
    signal(SIGINT, &handler);
    signal(SIGTERM, &handler);
    /* ... */
}

int handler() {
    free(buf1);
    free(buf2);
}
    
```

15

15

THE UNIVERSITY of NORTH CAROLINA at CHAPEL HILL COMP 790: OS Implementation

Nested Signals

- The original `signal()` specification was a total mess!
 - Now deprecated—do not use!
- New `sigaction()` API lets you specify this in detail
 - What signals are blocked (and delivered on `sigreturn`)
 - Similar to disabling hardware interrupts
- As you might guess, blocking system calls inside of a signal handler are only safe with careful use of `sigaction()`

16

16

THE UNIVERSITY of NORTH CAROLINA at CHAPEL HILL COMP 790: OS Implementation

Application vs. Kernel

- App: signals appear to be delivered roughly immediately
- Kernel (lazy):
 - Send a signal == mark a pending signal in the task
 - And make runnable if blocked with `TASK_INTERRUPTIBLE` flag
 - Check pending signals on return from interrupt or syscall
 - Deliver if pending

17

17

THE UNIVERSITY of NORTH CAROLINA at CHAPEL HILL COMP 790: OS Implementation

Example

```

int main() {
    read();
}

int usr_handler() { ...
    SIGUSR1);
}
    
```

Send signal to PID 300

18

18

THE UNIVERSITY of NORTH CAROLINA at CHAPEL HILL **COMP 790: OS Implementation**

Interrupted System Calls

- If a system call blocks in the INTERRUPTIBLE state, a signal wakes it up
- Yet signals are delivered on *return* from a system call
- How is this resolved?
- The system call fails with a special error code
 - EINTR and friends
 - Many system calls transparently retry after sigreturn
 - Some do not – check for EINTR in your applications!

19

19

THE UNIVERSITY of NORTH CAROLINA at CHAPEL HILL **COMP 790: OS Implementation**

Default handlers

- Signals have default handlers:
 - Ignore, kill, suspend, continue, dump core
 - These execute inside the kernel
- Installing a handler with signal/sigaction overrides the default
- A few (SIGKILL) cannot be overridden

20

20

THE UNIVERSITY of NORTH CAROLINA at CHAPEL HILL **COMP 790: OS Implementation**

RT Signals

- Default signals are only in 2 states: signaled or not
 - If I send 2 SIGUSR1's to a process, only one may be delivered
 - If system is slow and I furiously hit Ctrl+C over and over, only one SIGINT delivered
- Real time (RT) signals keep a count
 - Deliver one signal for each one sent

21

21

THE UNIVERSITY of NORTH CAROLINA at CHAPEL HILL **COMP 790: OS Implementation**

Signal Summary

- Abstraction like hardware interrupts
 - Some care must be taken to block other signals
 - Easy to write buggy handlers and miss EINTR
- Understand control flow from application and kernel perspective
- Understand basic APIs

22

22

THE UNIVERSITY of NORTH CAROLINA at CHAPEL HILL **COMP 790: OS Implementation**

Other IPC

- Pipes, Sockets, and FIFOs
- System V IPC
- Windows comparison

23

23

THE UNIVERSITY of NORTH CAROLINA at CHAPEL HILL **COMP 790: OS Implementation**

Pipes

- Stream of bytes between two processes
- Read and write like a file handle
 - But not anywhere in the hierarchical file system
 - And not persistent
 - And no cursor or seek()-ing
 - Actually, 2 handles: a read handle and a write handle
- Primarily used for parent/child communication
 - Parent creates a pipe, child inherits it

24

24

THE UNIVERSITY OF NORTH CAROLINA @ CHAPEL HILL COMP 790: OS Implementation

Example

```
int pipe_fd[2];
int rv = pipe(pipe_fd);
int pid = fork();
if (pid == 0) {
    close(pipe_fd[1]); //Close unused write end
    dup2(pipe_fd[0], 0); // Make the read end stdin
    exec("grep", "quack");
} else {
    close (pipe_fd[0]); // Close unused read end ...
}
```

25

25

THE UNIVERSITY OF NORTH CAROLINA @ CHAPEL HILL COMP 790: OS Implementation

FIFOs (aka Named Pipes)

- Existing pipes can't be opened---only inherited
 - Or passed over a Unix Domain Socket (beyond today's lec)
- FIFOs, or Named Pipes, add an interface for opening existing pipes

26

26

THE UNIVERSITY OF NORTH CAROLINA @ CHAPEL HILL COMP 790: OS Implementation

Sockets

- Similar to pipes, except for network connections
- Setup and connection management is a bit trickier
 - A topic for another day (or class)

27

27

THE UNIVERSITY OF NORTH CAROLINA @ CHAPEL HILL COMP 790: OS Implementation

Select

- What if I want to block until one of several handles has data ready to read?
- Read will block on one handle, but perhaps miss data on a second...
- Select will block a process until a handle has data available
 - Useful for applications that use pipes, sockets, etc.

28

28

THE UNIVERSITY OF NORTH CAROLINA @ CHAPEL HILL COMP 790: OS Implementation

Synthesis Example: The Shell

- Almost all 'commands' are really binaries
 - /bin/ls
- Key abstraction: Redirection over pipes
 - '>', '<', and '|' implemented by the shell itself

29

29

THE UNIVERSITY OF NORTH CAROLINA @ CHAPEL HILL COMP 790: OS Implementation

Shell Example

- Ex: `ls | grep foo`
- Implementation sketch:
 - Shell parses the entire string
 - Sets up chain of pipes
 - Forks and exec's 'ls' and 'grep' separately
 - Wait on output from 'grep', print to console

30

30

THE UNIVERSITY of NORTH CAROLINA at CHAPEL HILL **COMP 790: OS Implementation**

Job control in a shell

- Shell keeps its own “scheduler” for background processes
- How to:
 - Put a process in the background?
 - SIGTSTP handler catches Ctrl-Z
 - Send SIGSTOP to current foreground child
 - Resume execution (fg)?
 - Send SIGCONT to paused child, use waitpid() to block until finished
 - Execute in background (bg)?
 - Send SIGCONT to paused child, but block on terminal input

31

31

THE UNIVERSITY of NORTH CAROLINA at CHAPEL HILL **COMP 790: OS Implementation**

Other hints

- Splice(), tee(), and similar calls are useful for connecting pipes together
 - Avoids copying data into and out-of application

32

32

THE UNIVERSITY of NORTH CAROLINA at CHAPEL HILL **COMP 790: OS Implementation**

System V IPC

- Semaphores – Lock
- Message Queues – Like a mail box, “small” messages
- Shared Memory – particularly useful
 - A region of non-COW anonymous memory
 - Map at a given address using shmatt()
- Can persist longer than an application
 - Must be explicitly deleted
 - Can leak at system level
 - But cleared after a reboot

33

33

THE UNIVERSITY of NORTH CAROLINA at CHAPEL HILL **COMP 790: OS Implementation**

System V Keys and IDs

- Programmers pick arbitrary 32-bit keys
 - Use these keys to name shared abstractions
- Find a key using shmget(), msgget(), etc.
 - Kernel internally maps key to a 32-bit ID

34

34

THE UNIVERSITY of NORTH CAROLINA at CHAPEL HILL **COMP 790: OS Implementation**

Windows Comparison

- Hardware exceptions are treated separately from IPC
 - Upcalls to ntdll.dll (libc equivalent), to call handlers
- All IPC types can be represented as handles
 - Process termination/suspend/resume signaled with process handles
 - Signals can be an Event handle
 - Semaphores and Mutexes have handles
 - Shared memory equally complicated (but still handles)
- Single select()-like API to wait on a handle to be signaled

35

35

THE UNIVERSITY of NORTH CAROLINA at CHAPEL HILL **COMP 790: OS Implementation**

Summary

- Understand signals
- Understand high-level properties of pipes and other Unix IPC abstractions
 - High-level comparison with Windows

36

36
